

NHTSA DSFS Meta-Analysis

Dan Flynn

September 27, 2016

Background

Quantitative meta-analysis of the effectiveness of Dynamic Speed Feedback Signs (DSFS) in reducing driving speeds. Three sets of hypotheses are tested:

1. Activation of the signs. There are three way to carry out the test of activation: comparing before and during at the same site adjacent to the DSFS, upstream and adjacent during activation, or the difference from upstream to adjacent before to the difference from upstream to adjacent during.
2. Activation of the signs, donwstream. As above, there are muliple sets of comparisons for assessing activation effect downstream: comparing during downstream to before downstream, downstream and adjacent during activation, or a normalized difference.
3. Deactivation of the signs. We compare after and during at the same site

Articles were located from searches the databases TRID, National Transportation Library (NTL), WorldShare, Academic Search Complete, PsycINFO, Web of Science, and Science Direct. The searches were done between 3/9/2016 and 3/16/2016. Any of the search terms in the tables that ended in 's' were wildcards with *.

Activation hypothesis
